Subject: JAP: MS #JAP21-AR-DIS2022-05281R Decision Letter

Message: Dear Dr. Olikh:

I am pleased to inform you that your manuscript, referenced below, has been accepted for publication in the Journal of Applied Physics. Materials are being prepared for AIP Production Services.

"Features of FeB pair light-induced dissociation and repair in silicon n+-p-p+ structures under ultrasound loading" JAP21-AR-DIS2022-05281R

When your manuscript enters the production process, you will receive an email from the JAP production office with further instructions. Direct all questions pertaining to papers in the production process to the contact information supplied in that e-mail. Be sure to include your manuscript number (JAP21-AR-DIS2022-05281R) on all correspondence.

Please note that your manuscript will be evaluated during the production process to ensure that it meets the language standards for the journal. If your manuscript does not meet those standards you may be required to take further action before your paper can be published.

To track the status of your manuscript once it has entered the production process, login to the JAP submission site (https://jap.peerxpress.org/cgi-bin/main.plex) and click on the Manuscript ID link in the 'Manuscripts in Production' folder.

Thank you for your contribution to the Journal. If you have any questions, please feel free to contact us at jap-edoffice@aip.org.

Sincerely,

Jiangyu Li Associate Editor Journal of Applied Physics

phone: +1-516-576-2910 e-mail: jap-edoffice@aip.org

The appearance of your by-line and your author order of your data and your text is EXACTLY the way it will be printed. Review it carefully NOW to ensure you are completely satisfied. No modifications will be accepted in the event your article is to be accepted for publication. Please make any needed changes promptly.

Editor's Comments:

\*\*\*\*\*\*\* **Reviewer Comments:** 

Reviewer #2 Evaluations:

Does the manuscript present original and timely results that significantly advance the knowledge in applied physics: Yes

Does the manuscript report on convincing and rigorous data methods and analysis: Yes

Is the manuscript clearly written in correct English well organized and free from ambiguities: Yes

Is the title descriptive of the contents concise interesting and free of acronyms: Yes

Does the abstract adequately and clearly describe the contents (problem approach findings) of the paper: Yes

Are the figures in the manuscript necessary adequate well presented and clearly labeled: Yes

Is the reference list appropriate: Yes

The experimental research in ultrasound impact on iron--boron pair transformation insilicon n+-p-p+ structures has revealed the decrease in concentration of pairs dissociated by light, as well as in the time of pair associations. The FeB pair changes were monitored by measuring short circuit current kinetics. The ultrasound influence was investigated at different light intensities, temperatures, frequencies and power of acoustic wave. The possible mechanisms underlying the revealed effects were analyzed.

Properties of semiconducting structures are known to be determined very much by their impurity compositions. Iron is an important impurity in silicon--based solar cell technology; furthermore, iron-related defects are often transformed during the operation of appropriate devices. The present manuscript focuses on the experimental investigation of the influence of ultrasound loading of silicon solar cells on dissociation and repair of iron-boron pairs. It has been observed that ultrasound leads to a decrease in the association time and the concentration of light-dissociated pairs. We believe that using ultrasound for defect

engineering would be of interest to the journal's readers.

The Corresponding Author of a manuscript is required to advise the Editor when a revision of the manuscript carries a change in authorship (addition, deletion, or a change in order), and to explicitly cite the changes. In addition, if a change is made, all authors (including any that have been removed) will be sent an email containing a link which they will be required to follow in order to register their approval or

disapproval of the change. Authorship HAS NOT changed from the previous version of the manuscript.

**Invited Submission**

### 21 I. INTRODUCTION

It is of wide knowledge that the properties of semiconducting crystals and structures are determined very much by their impurity compositions. As a result, the methods aimed at modifying the system of defects are very important for practical applications. 26 Most of these methods use irradiation, thermal treatment, or specific conditions of crystal growth. However, numerous experiments show that ultrasound also represents a sufficiently effective instrument to control the semiconductor defects. For example, it has been found that acoustic waves cause a spatial redistribution of defects, 1-6 transformation of metastable point defects, 7-9 recharging of recombination centers, 10,11 and low temperature annealing of The effects of this kind are observed, in par-33 radiation defects. 12 34 ticular, in silicon, which is the basic modern material used in microelectronics and solar power engineering. 1,2,5,8,12,15,17,1

The advantages of using active ultrasound (US) are the local 37 action of elastic oscillations and the possibility to adjust the external impact by changing the type, polarization, or frequency of acoustic waves. 19 However, this method of modifying defect systems has not found wide application not least because of the lack of appropriate experimental research. In our opinion, it is 42 most promising to use US loading (USL) as an additional factor of influence during various technological processes, which causes, in 43 particular, the transformations in the defect system. This assumption is supported by the results obtained during ion implantation performed in the US field. 1,17,20

Iron is an important impurity in silicon-based integrated circuit and solar cell technology. Most often, iron-related defects are the main recombination centers that determine the lifetime of minority charge carriers, in particular, and device characteristics, in general. Therefore, the methods aimed at iron gettering at various stocks have practical importance. There are quite many reports concerning defects of this kind. It is known that in thermal equilibrium at room temperature virtually all Fe<sub>i</sub> is present as Fe<sub>i</sub>B<sub>s</sub> pairs in Si:B.<sup>21,22</sup> FeB pair dissociation can be accomplished by illumination at room temperature, by minority carrier injection, or by increasing the temperature. Moreover, ultrasound vibrations with a frequency of 25-80 kHz and acoustic lattice strain of  $10^{-5}-10^{-4}$  (Cz-Si<sup>25</sup>) or  $10^{-6}-10^{-5}$  (poly-Si<sup>26,27</sup>) are capable of destroying FeB pairs. In practice, however, the most widely used technique is light-induced dissociation. The peculiarities of the dissociation and subsequent repair are well studied. 21-23,28-33 However, to the best of our knowledge, there are no reports about the US impact on these processes.

**FIG. 1.** (a) Scheme of the sample. (1) frontal Al electrode, (2)  $\mathrm{Si}_3\mathrm{N}_4$ , (3)  $\mathrm{SiO}_2$ , (4) induced  $n^{++}$ -layer, (5) diffusion  $n^+$ -layer, (6) p-base region, (7) diffusion  $p^+$ -layer, and (8) rear Al electrode. (b) View of real solar cells; the photo was taken from the side of frontal metal electrode.

Our aim was to study experimentally the influence of ultrasound loading (2–30 MHz) on the processes of FeB  $\leftrightarrow$  Fe $_i$  + B $_s$ transformations in silicon solar cells (SCs). In order to prevent irreversible changes in the material properties, we used subthreshold intensity (strain  $< 2 \times 10^{-6}$ ). The obtained results can be applied for subtle acoustically controlled tuning of the processes involved in iron atom gettering.

#### 72 II. EXPERIMENTAL AND CALCULATION DETAILS

The  $n^+$ -p- $p^+$ -Si samples used in the experiment are shown in Fig. 1. The structure was fabricated from a 380  $\mu$ m thick p-type boron-doped Czochralski silicon wafer with [100] orientation and a resistivity of 10  $\Omega$  cm. The  $n^+$  emitter with a sheet resistance of about 20–30  $\Omega$ / and a thickness of 0.7  $\mu$ m was formed by phosphorus diffusion from the gas phase (POCl<sub>3</sub>) at 940 °C. The anti-recombination isotype barrier was created by using  $p^+$  layer (10–20  $\Omega$ /, 0.6  $\mu$ m) formed by boron diffusion from the gas phase (BCl<sub>3</sub>) at 985 °C. On the front surface, the antireflective and passivating SiO<sub>2</sub> (40 nm) and Si<sub>3</sub>N<sub>4</sub> (30 nm) layers were formed. The solid and grid Al contacts were formed by magnetron sputtering on the rear and front surfaces, respectively.

It has been found that some SC lots have significantly worse parameters compared to typical solar cells for this technological process. Additional experiments with thermal annealing at temperatures of 200 and 90 °C (the procedure is described by Tayyib *et al.*<sup>34</sup>) showed that a sharp drop in the photoconversion parameters value is caused by iron impurities available in the SC base at concentrations up to  $4 \times 10^{13}$  cm<sup>-3</sup> in the SC base. It has also been found that the source of iron impurity is insufficiently pure chemicals that were used in the technological process for some SC lots. To study the effect of ultrasonic loading on the transformation of iron–boron pairs, the samples from these "bad" lots with varying degrees of iron contamination  $[(0.2-4)\times 10^{13}~{\rm cm}^{-3}]$  were taken. The area of the samples used in the experiment was  $1.52\times 1.535~{\rm cm}^2$ .

To dissociate FeB pairs, the frontal side of the sample was illuminated with a halogen lamp with a radiation intensity  $W_{\rm ill}$  of 0.08–0.20 W/cm<sup>2</sup>. The illumination time  $t_{\rm ill}$  was up to 30 s.

The FeB pair association was monitored by measuring the kinetics of short circuit current  $I_{\rm SC}(t)$  after illumination by a halogen lamp—see Fig. 2.  $I_{\rm SC}$  was measured under SC illumination by a low-intensity monochromatic light source (light-emitting diode SN-HPIR940 nm—1 W with light wavelength  $\lambda=940$  nm). The excess carrier density  $\Delta n$  induced by the LED illumination was estimated by using open-circuit voltage value according to

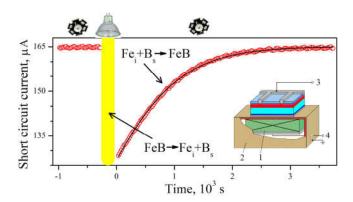

Sachenko *et al.*<sup>35</sup> The  $\Delta n$  value ( $<10^{12}$  cm<sup>-3</sup>) and duty cycle while 108  $I_{SC}(t)$  measuring (0.5%) evidence that LED illumination is weak 109 and does not cause FeB dissociation. After illumination by the 110 halogen lamp is terminated, FeB pairs are formed again and the 111 starting value of  $I_{SC}$  is completely recovered.

In fact, in conditions of homogeneous carrier generation in 113 the base, which is several minority carrier diffusion lengths  $L_n$ , the 114 short circuit current can be described as follows:  $^{36,37}$ 

$$I_{\text{SC}}(t) = \frac{P_{ph}(1 - R_{ph}) q\beta\lambda}{hc} \times \frac{\alpha_{ph} \sqrt{\mu_n k T \tau(t)/q}}{1 + \alpha_{ph} \sqrt{\mu_n k T \tau(t)/q}},$$
 (1)

where  $\alpha_{ph} = \alpha_{ph}(T, \lambda)$  is the coefficient of light absorption,  $P_{ph}$  is 116 the light power,  $R_{ph}$  is the coefficient of reflection,  $\beta$  is the coefficient of quantum yield,  $\mu_n$  is the electron mobility, and  $\tau$  is the 118 minority carrier lifetime in the base. In the assumption that it is 119 the iron-related defects that play an essential role in the recombination, the following expression can be used to estimate  $\tau$ : 121

$$\frac{1}{\tau(t)} = \frac{1}{\tau_i} + \frac{1}{\tau_{SRH}^{\text{Fe}_1}(t)} + \frac{1}{\tau_{SRH}^{\text{FeB}}(t)} + \frac{1}{\tau_{other}},\tag{2}$$

**FIG. 2.** Kinetics of short circuit current after intensive illumination. The marks are the experimental results, the line is the fitted curve using Eqs. (1)–(8). The zero of time corresponds to the moment of intensive illumination termination.  $T=340\,\mathrm{K}$ . Inset: Scheme of USL. (1) Piezoelectric transducer, (2) metal (Cu) foil, and (3 and 4) contact to I-V measure and to ultrasound excitation, respectively.

153

where  $\tau_i$  is the lifetime associated with intrinsic recombination;

 $au_{SRH}^{\mathrm{Fe_i}}$  and  $au_{SRH}^{\mathrm{FeB}}$  are related to the recombinations at interstitial iron

atoms Fe<sub>i</sub> and at FeB pairs, accordingly;  $\tau_{other}$  describes further

recombination channels (other impurities, lattice defects, surface

recombination). In order to calculate  $\tau_{SRH}^{Fe_i}$  and  $\tau_{SRH}^{FeB}$ , the Shockley-

Read-Hall model was used,

$$\tau_{SRH}^{\text{Fe},\text{FeB}}(t) = \frac{\tau_{p0}^{\text{Fe},\text{FeB}}(t) \times (n_0 + n_1^{\text{Fe},\text{FeB}} + \Delta n)}{N_A + n_0 + \Delta n} + \frac{\tau_{n0}^{\text{Fe},\text{FeB}}(t) \times (N_A + p_1^{\text{Fe},\text{FeB}} + \Delta n)}{N_A + n_0 + \Delta n},$$
(3)

where  $N_A$  is the material's doping level  $(1.4 \times 10^{15} \,\mathrm{cm}^{-3})$ ,  $n_0$  is the

equilibrium electron concentration given by the law of mass action,

and  $n_1$  and  $p_1$  are given by

$$n_1^{\text{Fe}_i,\text{FeB}} = N_C \exp\left(-\frac{E_C - E_t^{\text{Fe}_i,\text{FeB}}}{kT}\right),$$

$$p_1^{\text{Fe}_i,\text{FeB}} = N_V \exp\left(-\frac{E_t^{\text{Fe}_i,\text{FeB}} - E_V}{kT}\right),$$
(4)

131 where  $E_C$  and  $E_V$  are the energies of the conduction band and

valence band edge, respectively,  $N_C$  and  $N_V$  are the densities of

states in the conduction band and valence band, respectively, and

 $E_t$  is the energy level of the relevant defect. The respective capture

time constants of electrons and holes at the defect are given by

$$\tau_{p0}^{\text{Fe}_{i},\text{FeB}}(t) = \frac{1}{N_{\text{Fe},\text{FeB}}(t)\sigma_{p}^{\text{Fe}_{i},\text{FeB}}v_{th}^{p}}, 
\tau_{n0}^{\text{Fe}_{i},\text{FeB}}(t) = \frac{1}{N_{\text{Fe},\text{FeB}}(t)\sigma_{n}^{\text{Fe}_{i},\text{FeB}}v_{th}^{n}},$$
(5)

where  $N_{\text{Fe}}(t)$  and  $N_{\text{FeB}}(t)$  are the concentrations of Fe<sub>i</sub> and FeB,

respectively,  $v_{th}$  is the thermal velocity, and  $\sigma_n$  and  $\sigma_p$  are the respec-137

tive capture cross sections of electrons and holes at the defect.

The time dependence of interstitial iron atom concentration 139

after pair dissociation is described by the known expression from 140

Refs. 38 and 39, 141

$$N_{\rm Fe}(t) = (N_{\rm Fe,0} - N_{\rm Fe,eq}) \times \exp(-t/\tau_{\rm ass}) + N_{\rm Fe,eq},$$
 (6)

142 where  $\tau_{\rm ass}$  is the characteristic time of the complex association,

143 according to Refs. 23, 28, and 29

$$\tau_{\rm ass} = 5.7 \times 10^5 \, \frac{\rm s}{\rm K \, cm^3} \times \frac{T}{N_A} \exp\left(\frac{E_m}{kT}\right),\tag{7}$$

where  $E_m$  is the energy of Fe<sup>+</sup> migration,  $N_{\text{Fe},0}$  is the concentra-

tion of interstitial iron atoms formed due to illumination, and

 $N_{\rm Fe,eq}$  is the portion of interstitial iron atoms with  $N_{\rm Fe,0}$  that

remain unpaired in the equilibrium state. According to 147 Wijaranakula,  $^{39}$   $N_{\rm Fe,eq}$  depends on temperature, doping level, and  $N_{\rm Fe,0}$ :  $N_{\rm Fe,eq} = N_{\rm Fe,eq}(T, N_A, N_{\rm Fe,0})$ . The estimations show that at

149

340 K  $N_{\rm Fe,eq} \simeq 0.1 N_{\rm Fe,0}$  for the samples under study. 150

In its turn, the iron-boron pair concentration  $N_{\text{FeB}}$ , which is 151

formed as the result of the partial association of  $N_{\text{Fe},0}$ , can be

estimated from

$$N_{\text{FeB}}(t) + N_{\text{Fe}}(t) = N_{\text{Fe},0}.$$
 (8)

In case the intensive illumination causes dissociation of all the pairs, 154  $N_{\rm Fe,0}$  should be the same as the total concentration of the impurity 155 iron in the structure  $N_{\text{Fe,tot}}$ . If the duration (or intensity) of illumination is not sufficient for total dissociation,  $N_{\rm Fe,0} < N_{\rm Fe,tot}$ . In the 157 latter case,  $\tau_{other}$  will also make contribution in the recombination of 158 the FeB pairs that have not dissociated [with concentration  $N_{\text{Fe,tot}}$  159  $-N_{\rm Fe,0}-N_{\rm Fe,eq}(T,N_A,N_{\rm Fe,tot}-N_{\rm Fe,0})$ ] as well as the respective 160 number of Fe<sub>i</sub> [with concentration  $N_{\text{Fe,eq}}(T, N_A, N_{\text{Fe,tot}} - N_{\text{Fe,0}})$ ].

In our calculations, we took  $\beta=1$ ,  $R_{ph}=0.14$  (the result of 162 calculations according to Klyui *et al.* <sup>40</sup>),  $\mu_n(T, N_A)$  from Klaassen, <sup>41</sup> 163  $\nu_{th}^n$  and  $\nu_{th}^p$  from Green, <sup>42</sup>  $N_C$ ,  $N_V$  from Couderc *et al.*, <sup>43</sup> the defect 164 parameters from Rougieux *et al.*, <sup>44</sup> and  $\alpha_{ph}(T, \lambda)$  from data. <sup>45,46</sup> 165 In calculating  $\tau_i$ , band-to-band radiation recombination and Auger 166 recombination were taken into account, and the temperature 167 dependence of the corresponding coefficients was calculated 168 according to Nguyen et al.47 and Altermatt et al.48 We used 169 Eqs. (1)–(8) to fit the experimental data  $I_{SC}(t)$ . As fitting parameters,  $P_{ph}$ ,  $\tau_{other}$ ,  $N_{\text{Fe},0}$ , and  $E_m$  were taken. The fittings were per- 171 formed by using the metaheuristic method EBLSHADE. 49

The example of fitting results is shown in Fig. 2. In our case, 173 the parameters determined by fitting had the following values. 174  $P_{ph} = (3.6 \pm 0.2) \times 10^{-4} \,\mathrm{W}$ , which agrees well with the value 175 measured by PowerMeter Rk-5720 (3.5  $\times$  10<sup>-4</sup> W).  $\tau_{other} >$  100 s, 176 which testifies that the contribution of other recombination path- 177 ways can be neglected.  $N_{\rm Fe,0} = (1.6 \pm 0.1) \times 10^{13} \, \rm cm^{-3}$ , which is 178 close to the value obtained for the samples of the same series 179 from  $L_n$  measuring before and after intense illumination 180  $(0.5 \times 10^{13} \, \mathrm{cm}^{-3})$ . In this case,  $L_n$  was measured using spectral 181 dependencies of short circuit current<sup>50</sup> and the iron concentration 182 was determined by using Zoth and Bergholz<sup>24</sup> equation. Finally, 183  $E_m = (0.655 \pm 0.001) \,\text{eV}$ . This value coincides with that well-3,28,29,32 which is 0.66 eV. The coincidence of the 185 known value,2 values obtained by approximation with those obtained from other 186 sources (first of all,  $E_m$  value) proves that the investigations of 187  $I_{SC}(t)$  after intensive illumination can be applied for estimating 188 the parameters of iron-related defects. Moreover, the peculiarities 189 of pair dissociation (see Sec. III A) found in this way also correspond to those reported in the previous publications, which tes- 191 tifies that this approach is quite appropriate. In fact, the time of 192  $I_{\rm SC}$  recovering is an indicator of how large the energy of migration is, and the amplitude with which  $I_{SC}$  changes in the result 194 of intensive illumination is associated with the concentration of 195 iron atoms released in the process. It should also be noted that 196 this approach is similar to the method proposed by Herlufsen 197 et al.,<sup>51</sup> in which actual concentrations of FeB pairs are estimated 198 by the photoluminescence signal kinetics during association.

The measurements were carried out over a temperature range 201 of 300-340 K. The temperature was varied by a thermoelectric 202 cooler controlled by an STS-21 sensor and stabilized by a 203 computer-controlled PID loop.

In the case of USL, the transverse (with frequency 205  $f_{\rm US} = 0.3 \, \rm MHz)$  or longitudinal (2–31 MHz) acoustic waves (AWs) 206 were applied to the samples by using a piezoelectric transducer. The US intensities  $W_{\rm US}$  and amplitudes of strain  $\xi_{\rm US}=\frac{1}{209}$   $\sqrt{2W_{\rm US}/\rho_{\rm Si}\theta_{\rm US}^3}$  ( $\rho_{\rm Si}=2.33\,{\rm g/cm^3}$  is the silicon density,  $\theta_{\rm US}$  is the US velocity, 9850 and 5840 m/s in cases of longitudinal and transurers AWs, respectively) does not overcome 1.3 W/cm² and 2 × 10<sup>-6</sup>, respectively. Since the focus of our research was the influence of elastic vibrations on FeB pair transformations, to avoid the effect of the piezoelectric field, the transducer was shielded—see the inset of Fig. 2.

#### 16 III. RESULTS AND DISCUSSION

#### 217 A. FeB dissociation

218 In our investigation of light-induced FeB pair dissociation processes, we illuminated the structure with a halogen lamp by 219 varying the time of illumination  $t_{ill}$  and afterward measured the 220 kinetics of short circuit current recovery—see Fig. 3(a). As seen from the figure, the time of short circuit current recovery does not change while the amplitude of light-induced changes depends on the time of illumination. Further approximation of the experimen-225 tal curves by using the approach described in the previous section allowed us to estimate the number of pairs that dissociated in the 227 result of illumination  $N_{\text{Fe},0}$  as a function of  $t_{\text{ill}}$ . The experiments were carried out on a series of samples at different light intensities 228 and temperatures in conditions with and without US loading. The typical results are given in Fig. 4.

The obtained results show that as the illumination time grows the values of  $N_{\text{Fe,0}}$  increase gradually until reaching saturation. This is in complete correspondence with the results of the previous research studies  $^{21,23,28}$  that predict the exponential decrease in pair concentration with the increase in illumination time. The

saturation should correspond to the condition of complete pair dissociation. The experimentally obtained dependencies were approximated by using the following equation: 238

$$N_{\text{Fe},0}(t_{\text{ill}}) = A \exp(-t_{\text{ill}}/\tau_{\text{dis}}) + N_{\text{Fe},\text{fit}}, \tag{9}$$

where  $\tau_{\rm dis}$  is the characteristic time of dissociation and  $N_{\rm Fe,fit}$  is the 239 value corresponding to saturation. The examples of approximation 240 curves are given in Fig. 4, and the values of the parameters 241 obtained by approximation are given in Table I.

On the other way, the equilibrium between free  $Fe_i$  and  $Fe_iB_s$  243 is determined by the following rate equations:

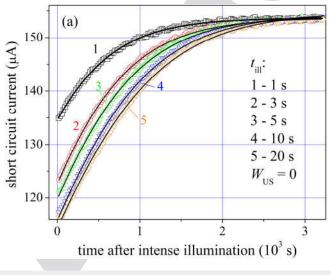

$$Fe_i + B_s \xrightarrow{R_a} FeB,$$

$$FeB \xrightarrow{R_d} Fe_i + B_s,$$
(10)

where  $R_a = \tau_{\rm ass}^{-1}$  and  $R_d$  are the association and dissociation rates of 245 FeB pairs, respectively. From Eq. (10), taking into account that 246  $N_{\rm Fe} = N_{\rm Fe,tot} - N_{\rm FeB}$  and  $N_{\rm Fe}(t_{\rm ill} = 0) = N_{\rm Fe,eq}$ , the time-dependent 247 interstitial iron content during illumination can be described as 248 follows:

$$N_{\text{Fe}}(t_{\text{ill}}) = \left(N_{\text{Fe,eq}} - N_{\text{Fe,tot}} \frac{R_d}{R_d + R_a}\right) \exp\left[-(R_d + R_a)t_{\text{ill}}\right] + N_{\text{Fe,tot}} \frac{R_d}{R_d + R_a}.$$
(11)

The comparison of Eqs. (9) and (11) shows that  $\tau_{\rm dis}^{-1}=R_a+R_d$ , 250  $N_{\rm Fe,fit}=N_{\rm Fe,tot}R_d/(R_a+R_dKd)$ . It should be noted that in our case 251 (see Sec. III B)  $\tau_{\rm ass}\gg\tau_{\rm dis}$  (without USL  $\tau_{\rm ass}\simeq700\,{\rm s}$  at 340 K and 252  $\tau_{\rm ass}\simeq13\,000\,{\rm s}$  at 300 K). Therefore,  $R_d\gg R_a$  and  $\tau_{\rm dis}^{-1}\simeq R_d$ , 253  $N_{\rm Fe,fit}\simeq N_{\rm Fe,tot}$ .

**FIG. 4.** Concentration dependence of interstitial atoms due to light-induced dissociation on illumination time. The marks are the experimental results and the lines are the curves fitted by using Eq. (9). Empty circles and solid lines are used for the case without USL, filled circles and dashed lines—for the case of USL.  $W_{\rm ill}$ ,  $W_{\rm cm}^2$ : 0.16 (curves 1–3, 8–11, 14, 15), 0.12 (4, 5, 16, 17), 0,09 (12, 13), 0.08 (6, 7, 18, 19).  $W_{\rm US}$ ,  $W_{\rm cm}^2$ : 0.9 (2, 5, 7), 0.6 (3, 9, 11, 13), 0.5 (15, 17, 19).  $f_{\rm US}$ , MHz: 9,0 (2, 3, 5, 7), 0.3 (9, 11, 13), 5,0 (15, 17, 19);  $T_{\rm cm}$ , K: 340 (1–9, 12–19), 320 (10,11). Samples SC350-1 (a), SC350-2 (b), and SC349-1 (c). Insets:  $\tau_{\rm dis}$  are plotted against  $W_{\rm ill}^{-2}$ . The lines are the curves fitted by  $\tau_{\rm dis}$  = constant  $\times W_{\rm ill}^{-2}$ .

As for the case without USL, we should note the following. First, for every sample  $N_{\rm Fe,fit}$  remains constant and does not depend on illumination intensity and temperature—see Table I. This is quite expectable if we assume that in this case  $N_{\rm Fe,fit} = N_{\rm Fe,tot}$ . Second, the value of  $\tau_{\rm dis}$  (last column in Table I) depends on  $W_{\rm ill}$  and T. It is well known  $^{21,28,52}$  that the dissociation rate of FeB pairs increases quadratically with increasing illumination intensity. In the insets of Fig. 4, the values of  $\tau_{\rm dis}$  are plotted against  $W_{\rm ill}^{-2}$ . The linearity of the obtained curves is in complete coincidence with the reported data and can serve as an additional proof of the suggested approach applicability in estimating iron-related defect parameters. Moreover, it is known that the dissociation time decreases approximately twice per 20 °C increase. In our experiment,  $\tau_{\rm dis} = (11 \pm 4)$  s for sample SC350-2 [Fig. 4(b) and Table I] at T = 320 K and at 340 K, it comprised 4.3  $\pm$  0.3 s, which justifies the expectations.

Another reason why it is advisable to analyze  $I_{SC}$  kinetics is the behavior of  $\tau_{other}$  revealed in the experiments. In the case when  $\tau_{ill}$  corresponds to the values of  $N_{\rm Fe,0}$  close to saturation, the other recombination channels can be neglected ( $\tau_{other} > 100~\rm ms$ ). In the case when the values of  $t_{ill}$  are small,  $\tau_{other}$  changes in the range  $10^{-6}-10^{-4}~\rm s$  and begins to increase as the illumination time increases. In terms of the proposed approximation, this indicates that some parts of FeB pairs have not dissociated and the value of  $\tau_{other}$  is related to recombination on iron-related defects that do not reconstruct when the sample is kept in darkness. In order to support this assumption, the quantity  $\tau_{other}^{calc}$  was estimated as follows:

$$au_{\textit{other}}^{\textit{calc}} = \left(\left( au_{\textit{SRH}}^{\text{Fe}_{i}}\right)^{-1} + \left( au_{\textit{SRH}}^{\text{FeB}}\right)^{-1}\right)^{-1},$$

where  $\tau_{SRH}^{Fe_{1}}$  and  $\tau_{SRH}^{Fe_{3}}$  were calculated by Eq. (3) for defect concentrations  $N_{Fe} = N_{Fe,eq}(N_{Fe,tot} - N_{Fe,0})$  and  $N_{FeB} = N_{Fe,tot} - N_{Fe,0} - N_{Fe,0}$  accordingly. It turned out that  $\tau_{other}^{calc}$  and  $\tau_{other}$ , obtained in the same conditions, are very close: the correlation coefficient equals to 0.98 (see the supplementary material).

Paying our attention back to the impact of acoustic waves on the processes of light-induced dissociation of FeB pairs, the following should be noted. First, USL actually does not influence 289 the magnitude of dissociation time:  $\tau_{\rm dis}$  values in neighboring rows 290 are similar in the error range for all the cases in Table I. Second, 291 some pairs do not dissociate under illumination in the USL case: 292

 $N_{\rm Fe,fit}(W_{
m US}>0) < N_{
m Fe,fit}(W_{
m US}=0)$ . How large the portion of these pairs is, depends on US intensity [see Figs. 4(a), Table I,  $W_{\rm ill} = 0.16 \, \rm W/cm^2$ ); at maximum  $W_{\rm US}$  values, this portion reaches 10%. It should be noted that this [effect] is observed only in the case when light-induced pair dissociation is close to saturation. 297 If  $W_{ill}$  (or temperature), however, is that at which a part of iron atoms stays near the substitutional boron atoms at the given illumi-299 nation times, then  $N_{\rm Fe,fit}(W_{\rm US}>0)\simeq N_{\rm Fe,fit}(W_{\rm US}=0)$ . 300

#### B. FeB association 301

302 It has also been found that USL accelerates FeB pair association, see Fig. 3(b). As seen from the figure, the main result of ultra-303 sound excitation in the structure is the decrease in time of short 304 circuit current recovery. Since in approximating experimental 305 dependencies  $I_{SC}(t)$ , we assumed that pre-exponential multiplier in Eq. (7) does not depend on USL (but relies only on the temperature 307 and level of base doping), in order to find numerical characteristics 308 of this effect, we used the change in migration energy  $\Delta E_{\rm US}$ , i.e., it was assumed that

$$E_m ultrasound E_{m,0} - \Delta E_{\rm US},$$
 (12)

where  $E_{m,0}$  is the migration energy estimated without USL and  $\Delta E_{\rm US}$  is the acoustically induced (AI) change in migration energy. It is seen from Fig. 3(b) that  $\Delta E_{\text{US}}$  depends on acoustic wave intensity. Figure 5 presents the dependencies  $\Delta E_{\rm US} = \Delta E_{\rm US}(W_{\rm US})$  at varied US frequencies and for the samples with different iron 315 content (estimated by the dependencies similar to those given in Fig. 4). The presented data show that 317

- 1.  $\Delta E_{\text{US}}$  shows a practically linear dependence on US intensity;
- 2. Effectiveness of AI change in migration energy decreases as the 319 US frequency increases; transverse waves, despite their low fre-320 quency, less strongly impact the processes of iron ion diffusion; 321
- 3. the magnitude of AI effect practically does not depend on iron 322 323 concentration:
- 4. AI change in migration energy can be as high as 13 meV. 324

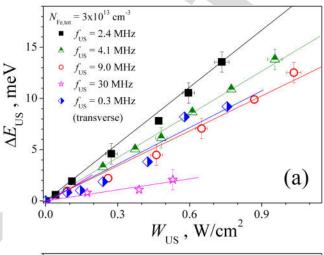

325  $\Delta E_{\rm US}$  has not been found to depend on illumination intensity. The data presented in Fig. 5 were obtained at 340 K. With the 326 decrease in temperature, the AI effect decreases—see Fig. 6. 327 As seen from the figure, temperature dependencies of  $\Delta E_{\text{US}}$  are 328 close to linear,

$$\Delta E_{\rm US}(T) = \Delta E_{\rm US}(0) + \alpha_{\rm US}T, \tag{13}$$

330 where temperature coefficient  $\alpha_{US}$  depends on US frequency (see the inset of Fig. 6), while  $\Delta E_{\rm US}(0)$  depends also on the US intensity.

#### C. Possible mechanisms of ultrasound influence

It is obvious that the analysis of the possible reasons for US 333 impact should be based on the mechanisms of iron-related defect 334 transformation. It is suggested that FeB pair dissociation is a twostage process.<sup>21,23,54</sup> First, the electron capture process leads to Fe<sub>i</sub> 336 neutralization, which removes the Coulombic attraction between Fe<sub>i</sub> 337 and B<sub>c</sub>. Second, the electron capture results in the deposition of diffusion barrier energy and spatial dissociation of atoms. In the

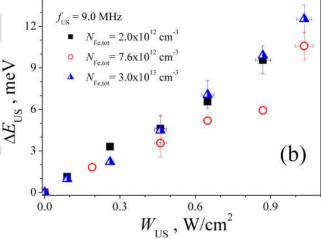

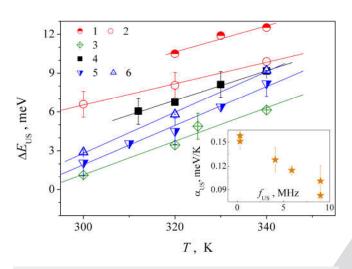

FIG. 5. Dependencies of Al change in migration energy on US intensity for various frequencies (a) and samples with different iron concentrations (b). T=340 K. The points were obtained by approximating experimental dependencies and the lines are the linear fitted curves.

literature, two possibilities are discussed: the second capture, which 340 leads to a negative charge state (Fe<sub>i</sub><sup>-</sup>) and consequently to 341 Coulombic repulsion of Fe<sub>i</sub> B<sub>i</sub> pair, and the second capture, which 342 deposits the necessary  $Fe_i^0$  migration energy after recombination with 343 a hole. The second way is known<sup>23</sup> as recombination-enhanced 344 defect reaction (REDR) and is caused by a strong electron-lattice 345 coupling at the defect.

As for the association, it happens due to  $Fe_i^+$  field-assisted 347 migration to  $B_s^-$ . Therefore, a more detailed expression for  $au_{ass}$  348 takes the following form:<sup>22</sup>

$$\tau_{\rm ass} = \frac{\varepsilon \varepsilon_0 kT}{q^2 D_{\rm Fe} N_A} = \frac{\varepsilon \varepsilon_0 kT}{q^2 D_{0, {\rm Fe}} N_A} \exp\left(\frac{E_m}{kT}\right),\tag{14}$$

(14)

**FIG. 6.** Temperature dependencies of  $\Delta E_{\rm US}$ .  $N_{\rm Fe,tot}$ ,  $10^{13}$  cm<sup>-3</sup>: 3.0 (curves 1 and 2), 4.3 (3), 1.9 (4).  $f_{\rm US}$ , MHz: 9.0 (1,2), 4.1 (3), 5.9 (4), 0.3 (5,6).  $W_{\rm US}$ , W/cm<sup>2</sup>: 1 (1), 0.87 (2), 0.48 (3), 1.0 (4), 0.58 (5), 0.76 (6). The marks are the experimental results and the lines are the linear fitted curves. Inset: Frequency dependence of temperature coefficient  $\Delta E_{\rm US}$ .

where iron diffusivity  $D_{\rm Fe} = D_{0,\rm Fe} \exp(-E_m/kT)$ , and in the general case<sup>55–57</sup>  $D_{0,\rm Fe} = \beta \nu a_0^2 \exp(\delta S_{\rm Fe}/k)$ ,  $\beta$  is the correlation factor,  $\nu$  is the effective vibrational (attempt) frequency,  $a_0$  is the jump distance, and  $\delta S_{\rm Fe}$  is the migration entropy.

For non-piezoelectric materials, the main effect of acoustic waves is associated with the mechanical stresses they cause. It is reported  $^{55,58-64}$  about several stress-related mechanisms of impurity diffusivity variation. For instance, Aziz *et al.*  $^{55,58}$  show that due to static stresses  $\sigma_{\text{stat}}$  in the crystal, the impurity migration energy can decrease by  $\Delta E = \sigma_{\text{stat}} V^*$ , where  $V^*$  is the activation strain tensor. It is known  $^{65}$  that as US propagates through the crystal, it causes static strain,

$$u_{\text{stat}} = \frac{\beta}{8} \left( \frac{2\pi f_{\text{US}} u_{\text{US}}}{v_{\text{US}}} \right)^2 = \frac{\beta W_{\text{US}}}{4\rho_{\text{SI}} v_{\text{US}}^3},$$
 (15)

 $\beta$  is the acoustic nonlinearity parameter  $u_{\rm US}=\frac{1}{\pi f_{\rm US}}\sqrt{\frac{W_{\rm US}}{2\rho_{\rm Si}\nu_{\rm US}}}$  is the amplitude of lattice atom displacements. 364 Therefore, the effect should be linear with respect to the US intensity, which correlates with the experimental data. It is known, <sup>58</sup>, 365 however, that  $V^* = (0.01 - 0.2)\Omega$ , where  $\Omega$  is the atomic volume 366  $(\sim\!\!2\times10^{-29}\,\text{m}^3$  for silicon), and the value of the multiplier 368 depends on the kind of impurity. If we consider the propagation of longitudinal waves in direction [100] ( $\beta = 2.0003$  is assumed, 369  $\sigma_{\text{stat}} = c_{11}u_{\text{stat}}, \quad c_{11} = 166 \text{ GPa}, \quad \text{for} \quad W_{\text{US}} = 1 \text{ W/cm}^2 \quad \text{we shall}$ 370 obtain  $\Delta E = 5 \times 10^{-11}$  eV. Therefore, this mechanism cannot be 371 372

372 the cause of the revealed effect.
373 According to the data, 60-62 the diffusion of impurities in US
374 fields can occur due to elastic deformation. In particular, the
375 energy of interaction between a single defect and the strain field is

$$E_{\rm int}(x,t) = -K\Omega_d \xi(x,t), \tag{16}$$

where K is the bulk modulus (102 GPa for Si),  $\Omega_d$  is the variation 377 of crystal volume, in the result of point defect formation, for interstitial defect  $\Omega_d = (1.7-2.2)\Omega$ , and  $\xi$  is the lattice relative deformation by the acoustic wave. The estimation of maximum 380 interaction for  $W_{\rm US} = 1\,{\rm W/cm^2}$  yields  $E_{\rm int} \simeq 0.1\,{\rm meV}$ . Although 381 Baransky *et al.* 68 state that in case of clusters containing  $N_t$  defects, 382 a collective effect can be observed, when  $E_{\rm int} \to N_t E_{\rm int}$ , in our 383 opinion, this mechanism cannot be crucial in the effect of AI acceleration of FeB pair association revealed in our research.

In turn, the most probable cause of a decrease in  $\tau_{\rm ass}$  is the 386 process of impurity interactions with nonequilibrium excitations of 387 the crystal lattice described in Refs. 63 and 64, which results in the 388 change in probability of diffusion transitions. According to 389 Pavlovich, 63 the US influence is that it causes an increase in crystal 390 effective temperature and an effective decrease in "polaron" activation energy. The latter is related to the transfer of lattice deformation around the impurity during diffusion transition. 31 It should be 393 noted that according to calculations, 63 this effect should depend 394 linearly on US intensity and temperature, which correlates with 395 experimentally found peculiarities of AI changes. In addition, 396 according to Krevchik *et al.*, 64  $\Delta E_{\rm US} \sim t_s$ , where  $t_s$  is phonon collision time, which can account for the revealed frequency dependence of the effect.

It should be noted that the iron-boron pairs are found<sup>25-27</sup> to 400 dissociate due to ultrasound treatment. In our opinion, the reported 401 herein and previous results have a lot in common. In fact, accord- 402 ing to Ostapenko et al.,26 Fei has to "jump" to the next nearest 403 interstitial under ultrasound action; we state about the decrease in 404 Fe<sub>i</sub> migration energy value as well as the enhance of Fe<sub>i</sub> diffusivity 405 in case of ultrasound loading. Further, the efficiency of AI dissocia- 406 tion, as well as AI  $\tau_{ass}$  fall, increases with the rise of temperature. 407 The difference in the action of ultrasound (the iron-boron pairs 408 dissociation or the enhancing of pairing) is associated with the dif- 409 ference in the intensity of the acoustic influence. For instance, the 410 researchers used acoustic strain  $\xi_{\rm US}=10^{-5}$  –  $10^{-4}$  was used  $^{25}$  to dissociate FeB pairs in Cz-Si. Furthermore, Ostapenko and Bell<sup>25</sup> 412 regarded the resonance condition of pair reorientation (first step of 413 dissociation) and used 25–70 kHz. In our case,  $\xi_{\rm US} < 2 \times 10^{-6}$  and 414  $f_{\rm US} = 2-30 \, \rm MHz$  are deficient to effectively overcome the 415 Coulombic attraction between  $Fe_i^+$  and  $B_s^-$ . Additionally, the presented data show that the effectiveness of acoustically induced 417 change decreases as the ultrasound frequency increases. Besides, it 418 should be noted that Ostapenko et al.<sup>27</sup> asserted that in the case of 419 predominant dissociated pairs, the ultrasound treatment may 420 promote the pairing reaction in contradistinction to the case of a 421 high fraction of paired iron. In our case, the predominant dissocia- 422 tion was realized by intense illumination and then the ultrasound 423 loading accelerated pairing. Thus, the reported results provided 424 empirical evidence for the above-mentioned prediction.

As far as dissociation is concerned, it is worth paying attention 426 to the possible US impact on the processes of charge carrier 427 capture. For instance, it is suggested that in conditions of USL 428 the capture cross sections for complex defects should change 429

531

because of the change in effective distance between the components. In particular, this effect is expected to be especially substantial for the complexes whose components have  $\Omega_d$  with opposite signs. This is what is observed for FeB ( $\Omega_d(Fe_i) > 0$ ,  $\Omega_d(B_s) < 0$ ) 433 and for this reason, the complex should be acoustically active in 434 terms of charge carrier capture. However, in our opinion, the processes of AI changes in  $\sigma_{n(p)}$  should have influenced, first, the char-436 acteristic time of dissociation, but actually, the effects of this kind 437 have not been revealed. AI increase of  $R_a$  should decrease  $N_{\rm Fe,fit}$ 438 [see Eqs. (9) and (11)]; however, this effect is leveled by the essential difference between  $\tau_{\rm dis}$  and  $\tau_{\rm ass}$ . Therefore, probably because of 440 this reason, the US produces an impact on the second stage of dis-441 sociation. On the one hand, Korotchenkov and Grimmeiss<sup>11</sup> show 442 that due to the change of impurity location concerning surround-444 ing atoms in silicon under USL, the activation thermal energy of the carrier captured by the defect is decreased (up to about 10 meV 445 at US intensities commensurate to those in our experiments). A similar increase in electron emission in our case should decrease the equilibrium part of negatively charged Fe ions experiencing Coulombic repulsion with  $B_s^-$ . On the other hand, it is shown 449 450 that USL of low intensity makes some part of the FeB pairs get rearranged in a metastable configuration with a different (ortho-452 rhombic) symmetry, in which the distance between the components is greater. At over threshold US intensities, the spatial 453 separation of this kind results in a complete pair dissociation. For our case, however, the important thing is that the decrease in distance weakens the Coulombic repulsion. In addition, the decrease in the concentration of pairs, which dissociate under illu-457 mination in the USL case, can be connected to a partial acoustically induced FeB dissociation. In fact, if some pairs were dissociated by 460 ultrasound waves, which had been pre-exited in the sample with a high initial fraction of paired Fe, they cannot be dissociated under 461 illumination. The decrease in the temperature or photon quantity leads to a reduction in the set of FeB which was modified by ultra-464 sound or in the set of FeB which was modified by the capture of light-induced electrons, respectively. The sets cease to overlap and 465  $N_{\rm Fe,fit}(W_{\rm US}>0)\simeq N_{\rm Fe,fit}(W_{\rm US}=0)$ —see Table I. Finally, USL can be the cause of weakening the electron-lattice coupling at the 467 defect as well as the REDR process as a whole. 468 469

Numerous publications, see, for example, Refs. 70–72, report that during such technological processes as temperature stimulated diffusion of dopants or the formation of an antireflection coating, iron atoms also undergo gettering. This is caused by Fe ions diffusion to various stocks. When performed in the US field, these processes, as the obtained results suggest, should improve the gettering effectiveness because of the greater volume from which Fe ions could be piled at the stocks.

#### 77 IV. CONCLUSION

The experimental research of ultrasound impact on the pro-479 cesses of FeB pair transformation was carried out in silicon 480  $n^+$ -p- $p^+$  structures at near room temperatures. The investigation 481 has revealed an acoustically driven decrease in the portion of FeB 482 pairs that dissociate under the action of light as well as the decrease 483 in Fe ion migration energies. The latter effect depends linearly on 484 ultrasound intensity; the temperature decrease and ultrasound frequency increase reduce the acoustically induced change of 485 migration energy. The analysis has shown that these phenomenons 486 are caused by the interaction of impurities with nonequilibrium 487 excitations of a crystal lattice, and acoustically driven attenuation of 488 Coulombic repulsion, which is caused by the increase in distance 489 between pair components and/or change in defect's charge. Thus, 490 ultrasound can be an effective tool for controlling silicon structure 491 characteristics.

#### SUPPLEMENTARY MATERIAL

See the supplementary material for the lifetime associated 494 with further recombination channels plot [ $\tau_{other}$  which was 495 obtained by  $I_{SC}(t)$  fitting vs  $\tau_{other}^{calc}$  which was calculated from  $N_{Fe,0}$  496 and  $N_{Fe,fit}$  values].
